Introduction:

In this document the results of a Fuzzy cognitive mapping exercise conducted at the 2009 ALTER-Net Summer School in Peyresq are presented. 29 maps were produced by the participants trying to answer the “easy” question:

“What factors will lead to a change in the natural environment and how will that effect human well-being”.

The attempts of the participants (and tutors) to find a response to this question can be found on these pages. The document has three main parts, the first giving an overview over all maps, the second introducing the aggregated map and some results of the dynamical analysis (simulation) of this map and finally the third part contains all individual maps & their indices.

This document mainly lists the results of the mapping and does not discuss them in depth. Feel free to take your own conclusions out of your maps! Additional material like the net-files & the adjacency matrixes will also be made available on www.FCMappers.net.

Fuzzy Cognitive Mapping

In the following a short overview over the FCM indices is given:

Indices:

Density (D) shows how highly connected the factors are to each other within the network. It is calculated by dividing the number of counted connections (C) by the number of possible connections between N factors (Hage & Harary 1983).

Equation 1: If no self-feedback is allowed (main diagonal consist solely of zero) max. number of connections is $N(N-1)$ if factors are allowed to influence themselves than there are N^2 possible connections within a network.

$$D = \frac{C}{N(N-1)} \quad D = \frac{C}{N^2}$$

More connections per concept will result in a higher density (D). A system with higher density is seen as containing more available options to manipulate the system (Özesmi & Özesmi 2004).

To define the type and the role of each factor within the network Indegree, Outdegree and Centrality are calculated.

Indegree [id(vi)] is calculated by summing up the absolute values of all ingoing arrows (the sum over the column of a factor in the matrix). **Outdegree** [od(vi)] is calculated by summing up the absolute

values of all out going arrows (the sum over the row of a factor in the matrix). Absolute values give positive and negative values equal importance (Yaman & Polat 2009).

$$\text{id}(v_i) = \sum_{k=1}^N \bar{a}_{ki}$$

$$\text{od}(v_i) = \sum_{k=1}^N \bar{a}_{ik}$$

The **centrality** or total degree (Harary et al., 1965) of a factor is the sum of the in- and outdegrees. In FCMs, unlike cognitive maps or some SNA approaches, the value of centrality of a factor can be higher although it has fewer connections than others, as the weight of the connections enters the calculation of centrality (Kosko 1986). Centrality is a measure for the importance of a node. Concepts with high centrality-values should therefore get special attention (Yaman & Polat 2009).

Three different types of factors can be found in a FCM: transmitter, receiver and ordinary. Transmitters have positive outdegree but no indegree. They impact the system but the system does not directly affect them they act as drivers or forcing functions. Receivers have a positive indegree but zero outdegree, and are also called end. Ordinary factors have both positive in- and outdegrees (Harary et al 1965).

Complexity is the ratio of the number of transmitters to the number of receivers. It shows if the system is rather externally or endogenously driven (Eden et al. 1992). If the quotient of receivers / transmitters is high, complexity is high. If this quotient is low, it shows that the system is perceived as rather out-side driven with little bottom-up control (Simon 1996, p 185).

Social Map:

A social map is a map produced through augmenting several FCMs through matrix addition. In contrast to an “Cognitive Interpretation Diagram” the concepts of a social map are only augmented if they express the same meaning. For example “Farming” and “Agriculture” can be fused into one concept while “Biodiversity” and “Species Diversity” will not – as these concepts have similar but different meaning. The aim of a social map is to conserve the richness of the individual maps. The resulting map usually contains too many nodes to be visually interpreted in a meaningful. It is the basis of the dynamic analyses (Özesmi & Özesmi 2004).

Dynamic Analysis:

With the dynamic analysis the steady state of the system can be determined and scenarios can be calculated. As described in Özesmi & Özesmi (2004) we use the auto-associative neural network method (Reimann 1998). A vector of initial states of variables is multiplied with the adjacency matrix of the social map. Through the connections input is transmitted from one node to the next connected node(s) according the strength attributed to this connection. The output is scaled in the interval of 0-1 by using a logistic function. The multiplication is iterated until the network converges to a fixed point. This results in the steady state of the network.

When running scenarios some factors (concepts) are set to high respectively low values. The results of a Scenario run is then compared to the steady state results to see if the value of the concept has increased or decreased i.e. if the factor shows a positive or a negative trend compared to the reference scenario.

Software

For calculating the indices, running the scenarios and transforming the adjacency matrix into a net-file format “FCMapper” was used. To produce the network images and to extract sub-networks the social-network software “Pajek” and “Visone” were used. The material needed to repeat all the calculations presented here will be made available on www.FCMappers.net. Here you can also find the links to the social network software and a short tutorial on how to use Pajek to open your net-files.

Results

Overview

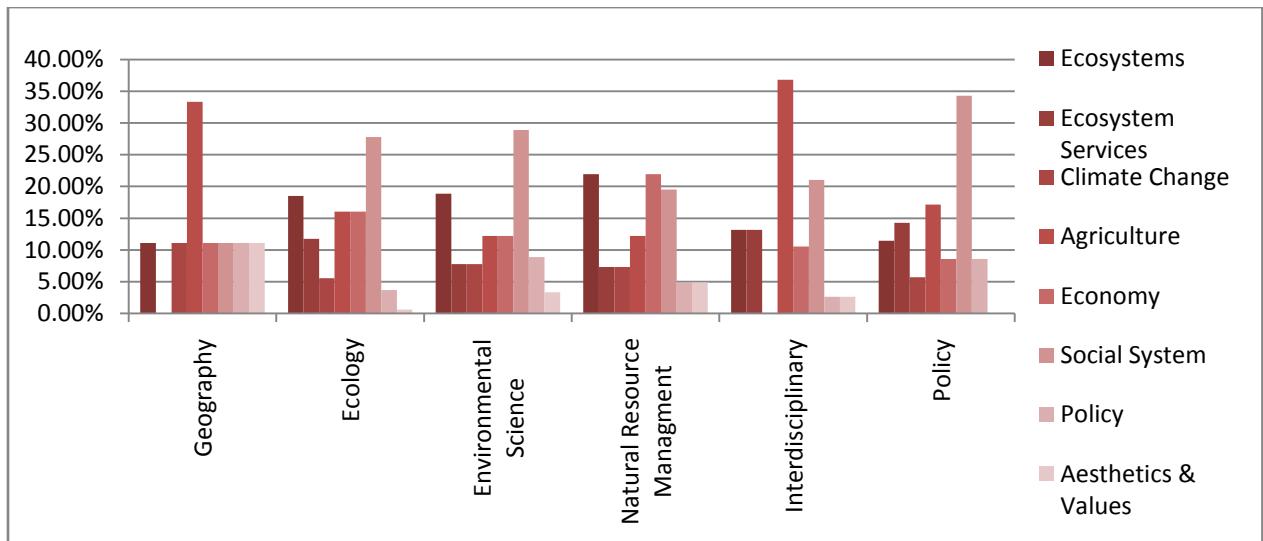

Figure 1: Distribution of concepts (grouped into 8 thematic groups) over the 6 disciplines.

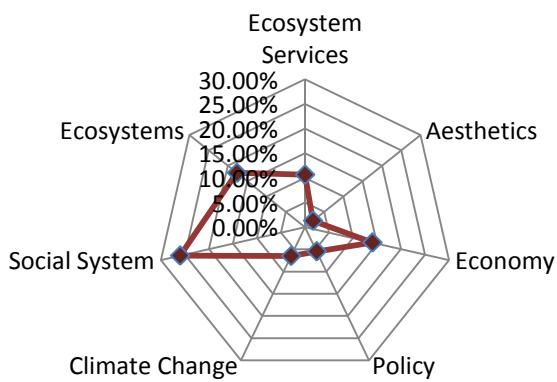

Figure 2: Fraction of concepts in the eight different thematic groups. Most concepts (26%) can be related to the social system.

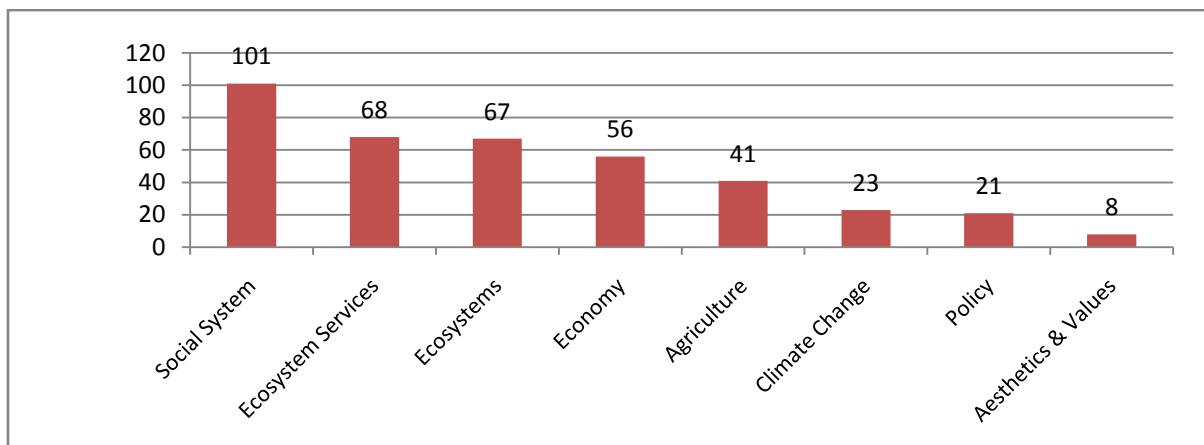

Figure 3: Total number of concepts in the eight different thematic groups.

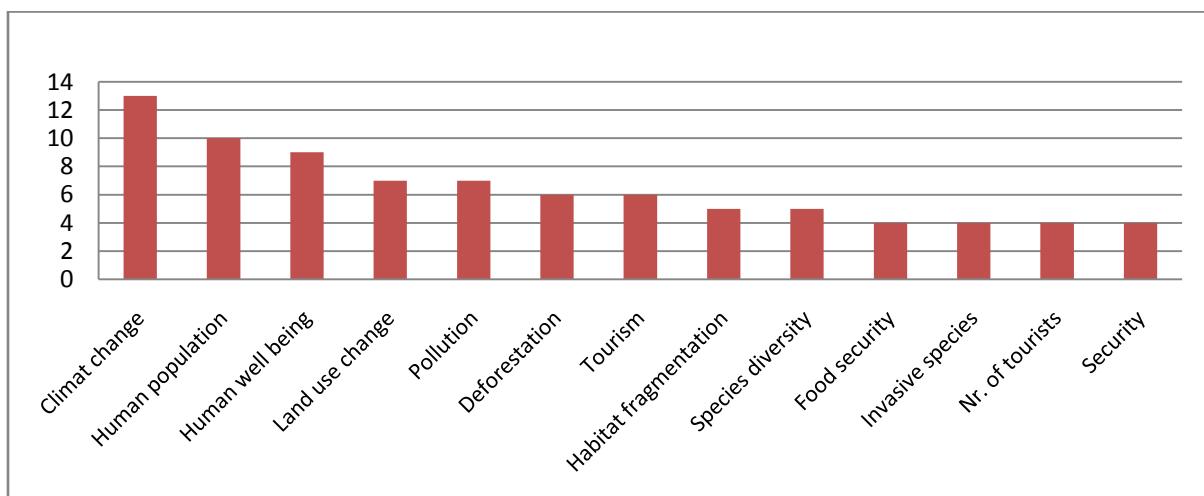

Figure 4: The most mentioned concepts in the 29 maps. Concepts mentioned at least four times were included into the graphic.

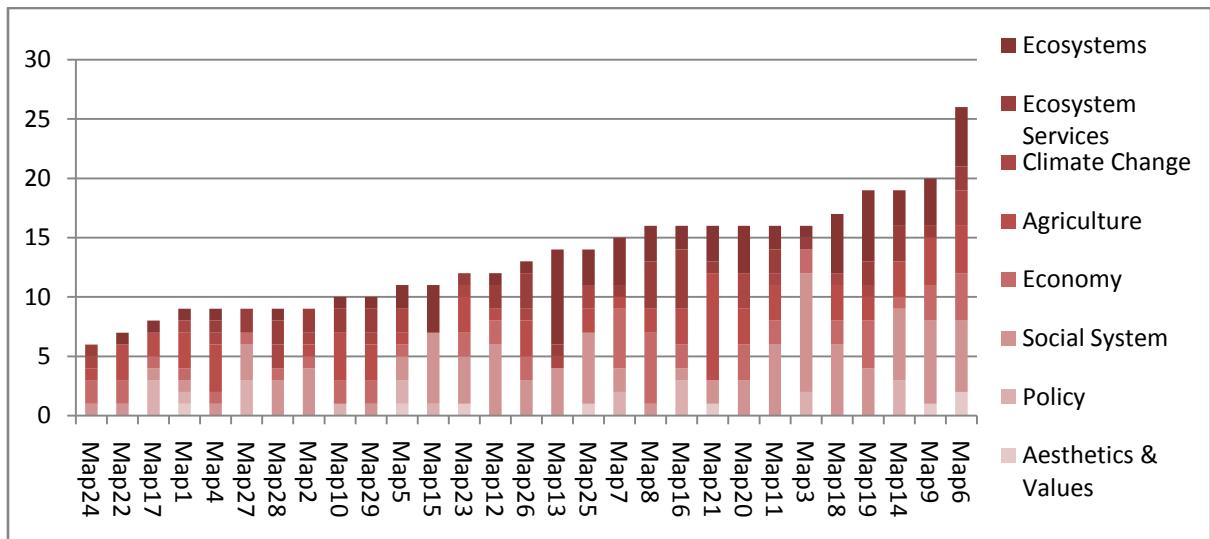

Figure 5: Maps with the number of concepts per map and their distribution into the eight thematic groups.

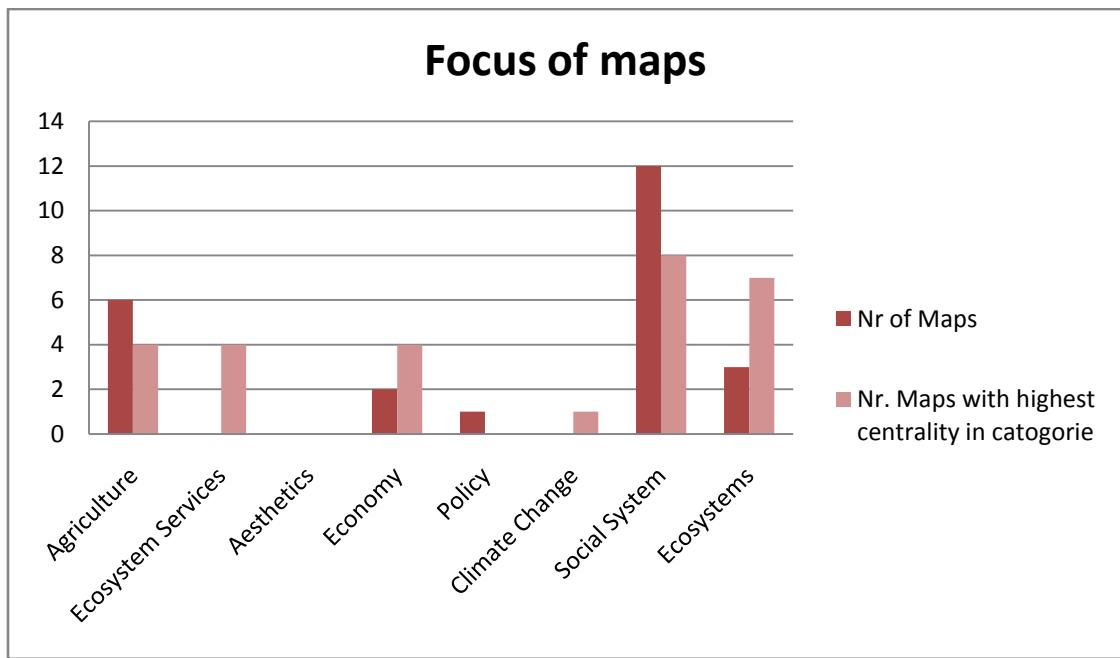

Figure 6: The dark red bar shows the number of maps in which concepts belonging to the thematic category dominate. The light red bars show the number of maps in which a concept belonging to a certain thematic category is the most central concept.

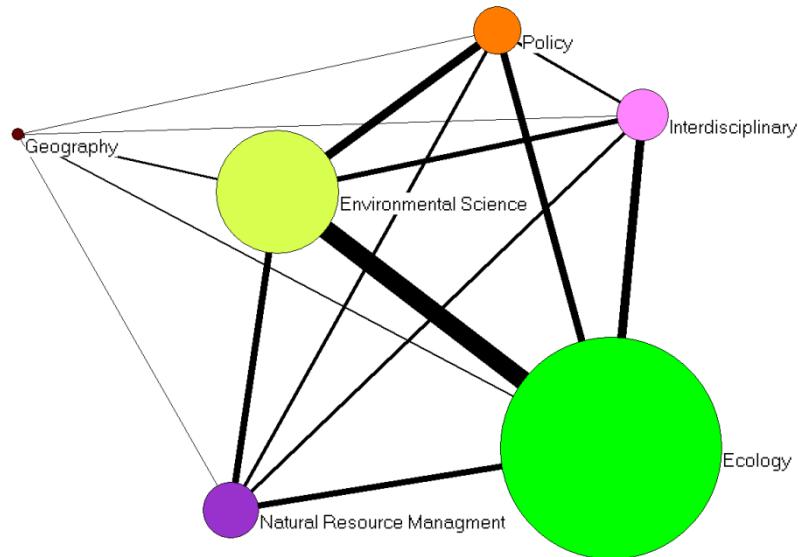

Figure 7: Graphic representation of overlap between maps grouped into the disciplinary background of the creator. The size of the circles represents the number of concepts counted in the maps of the respective discipline; the width of the line represents the number of similar concepts between the disciplines.

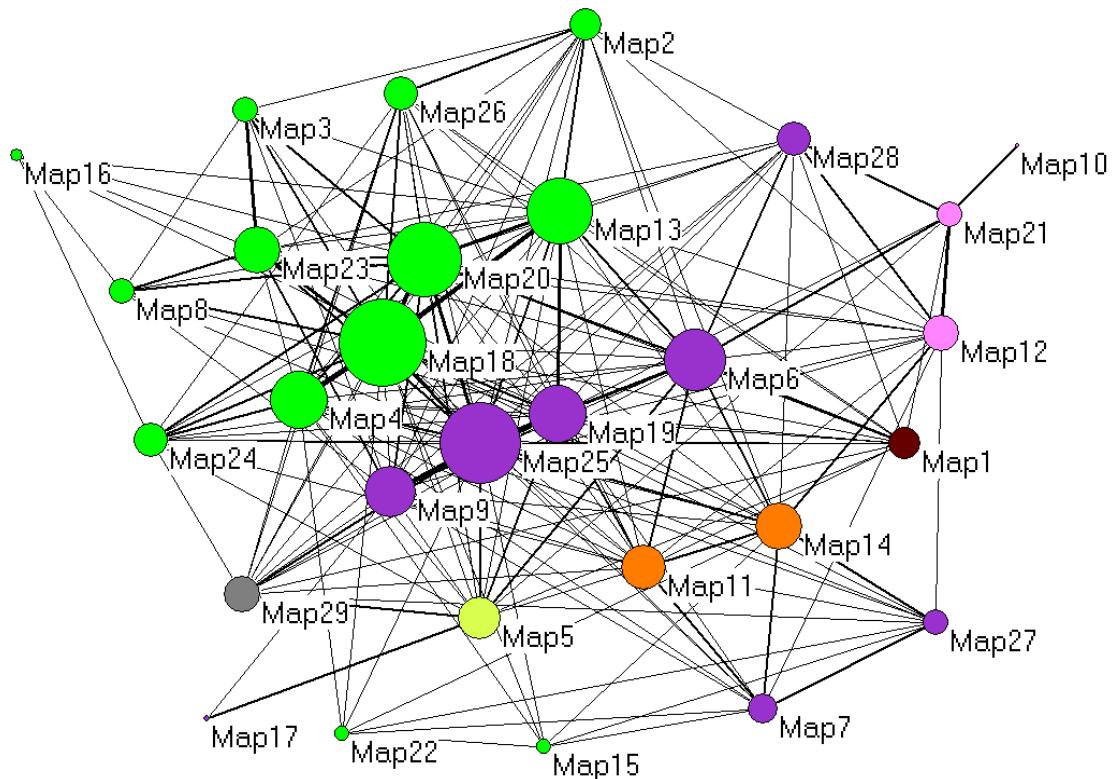

Figure 8. Overlap between the single maps. The colors of the circles represent the disciplines they belong to (see figure 7 for color code – gray = discipline not known). The size of the map represents the amount of shared concepts.

The Aggregated map and the dynamic analysis

All complete maps ($n = 25$) were aggregated into one big social map using the aggregation tool of FCMapper. Concept-names were only aligned if synonyms or different spelling was used. The aggregation resulted in a map containing 226 concepts. This map will be our basis to run dynamic analysis & scenarios.

Table 1: Basic figures of the aggregated map

Density	Total No. Factors	Total No. Connections	No. Transmitter	No. Receiver	No. Ordinary	Complexity
0.012	226	579	32	25	169	1.28

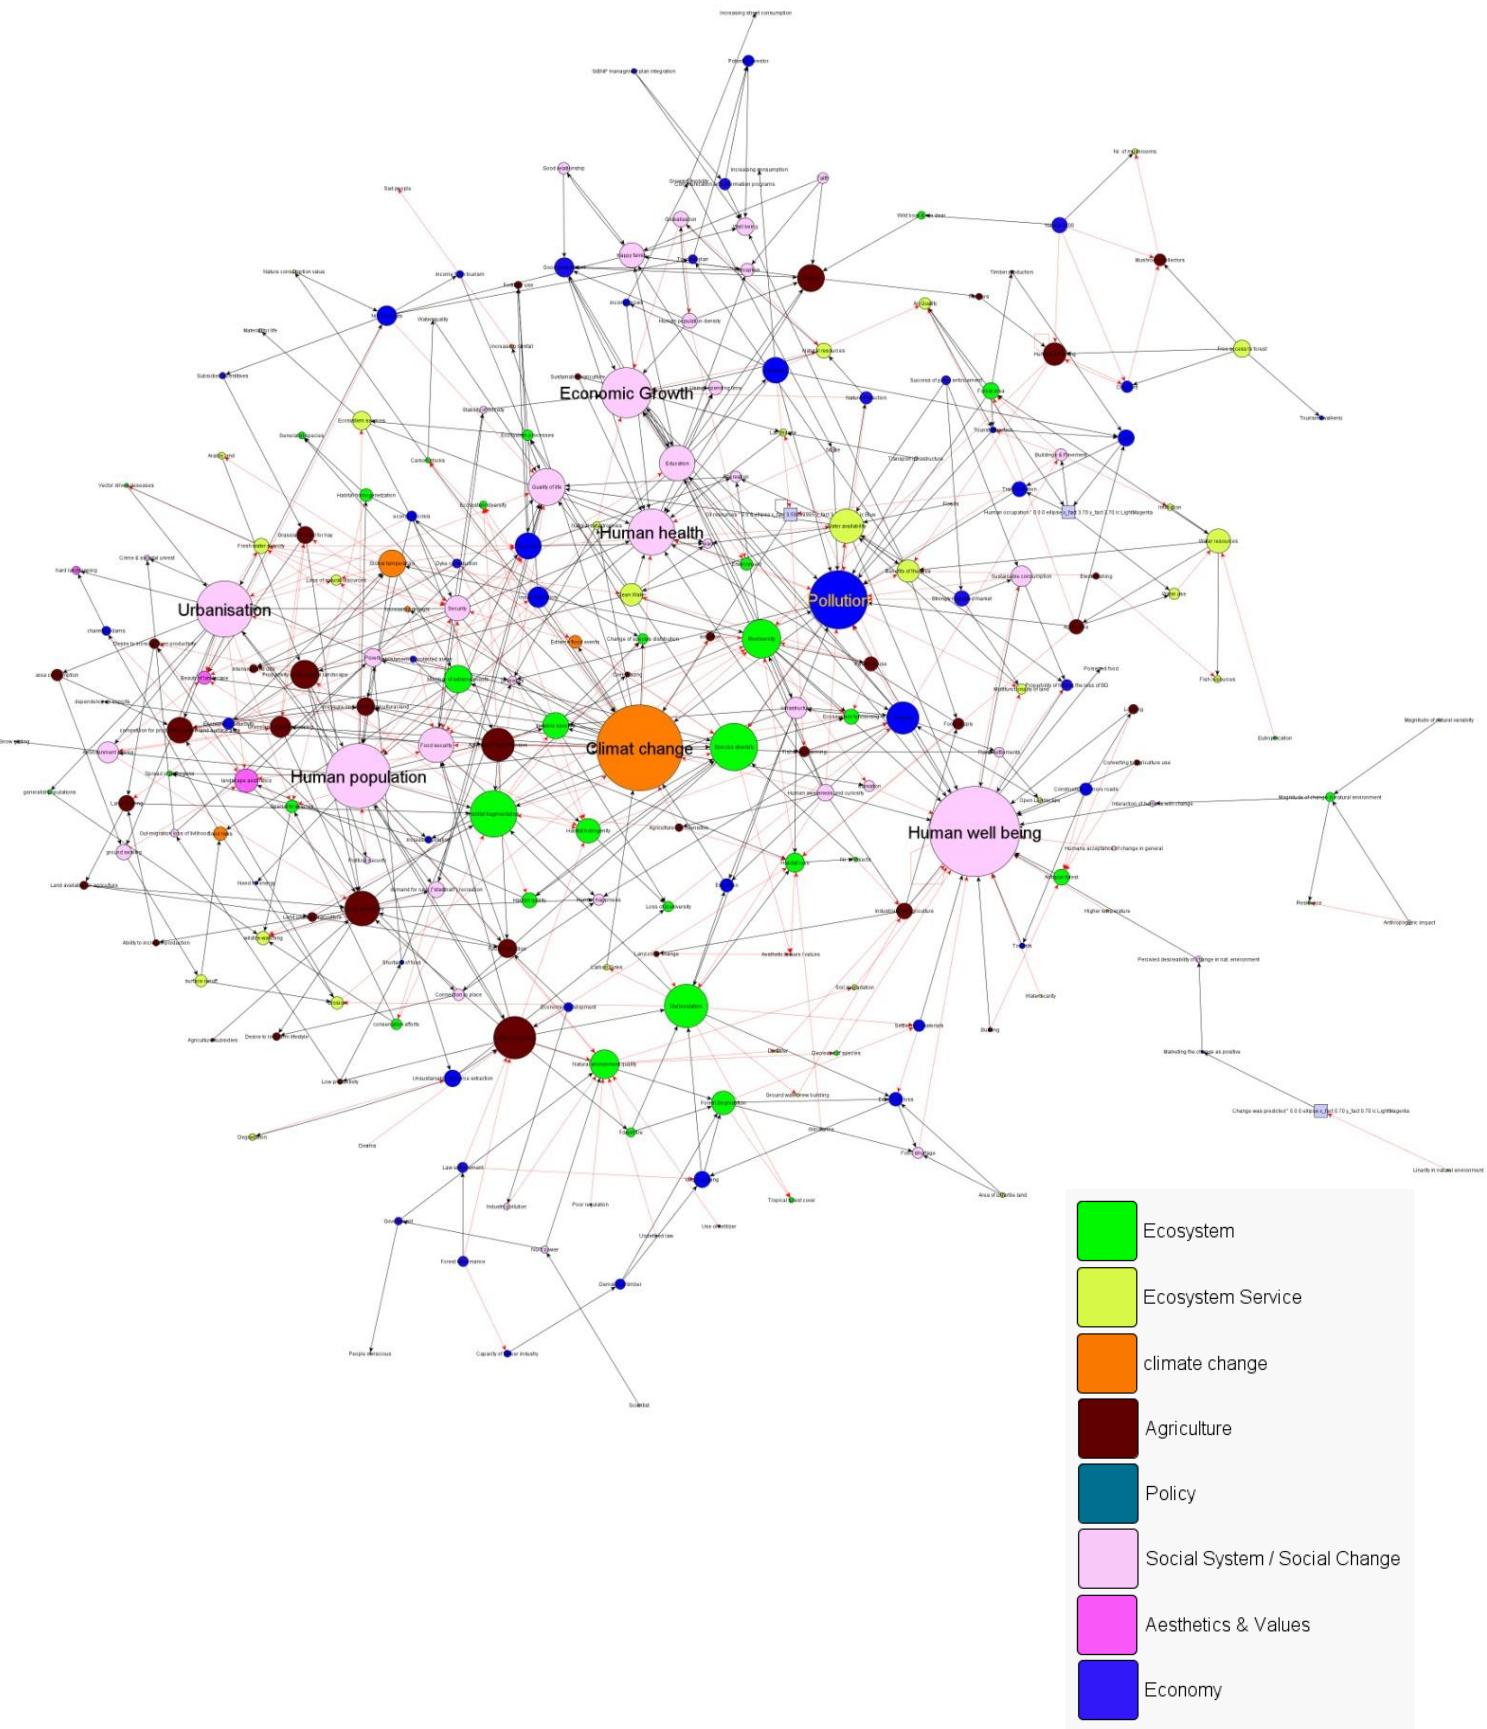

Figure 9: The aggregated social map with its 226 concepts. The same color code is also used in all following maps.

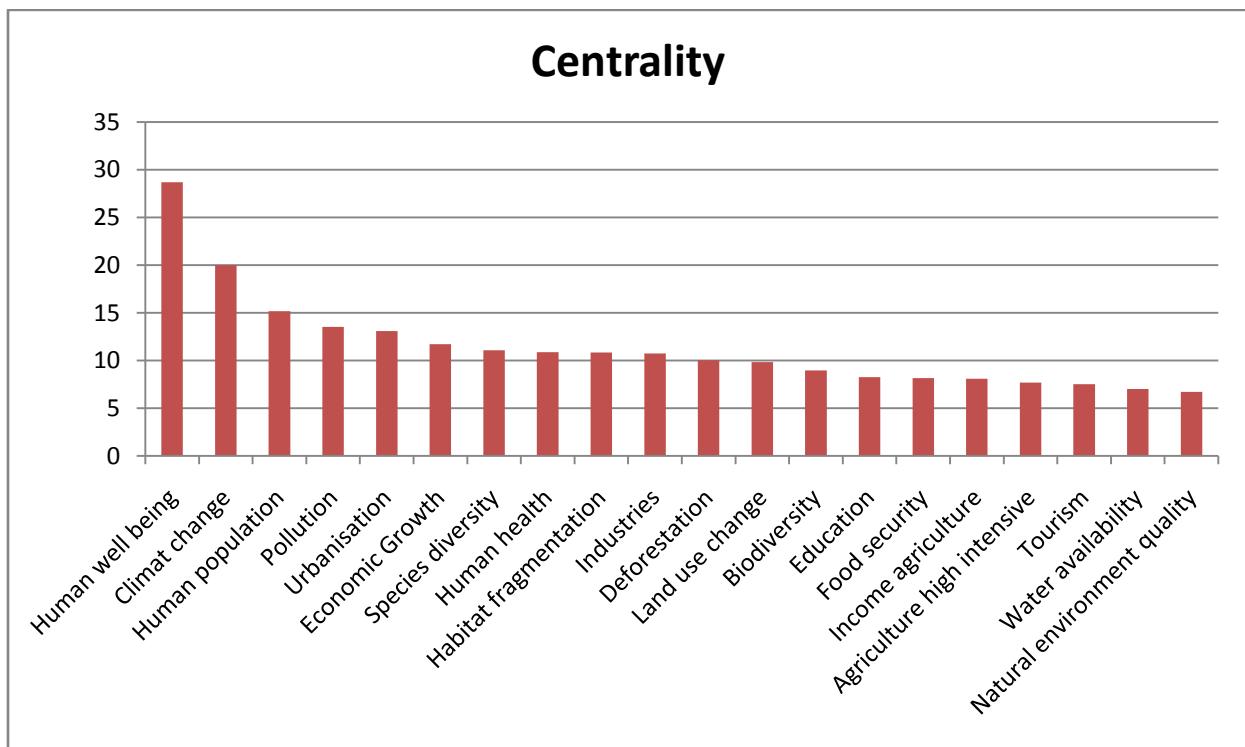

Figure 10: Concept with highest centrality in the aggregated map

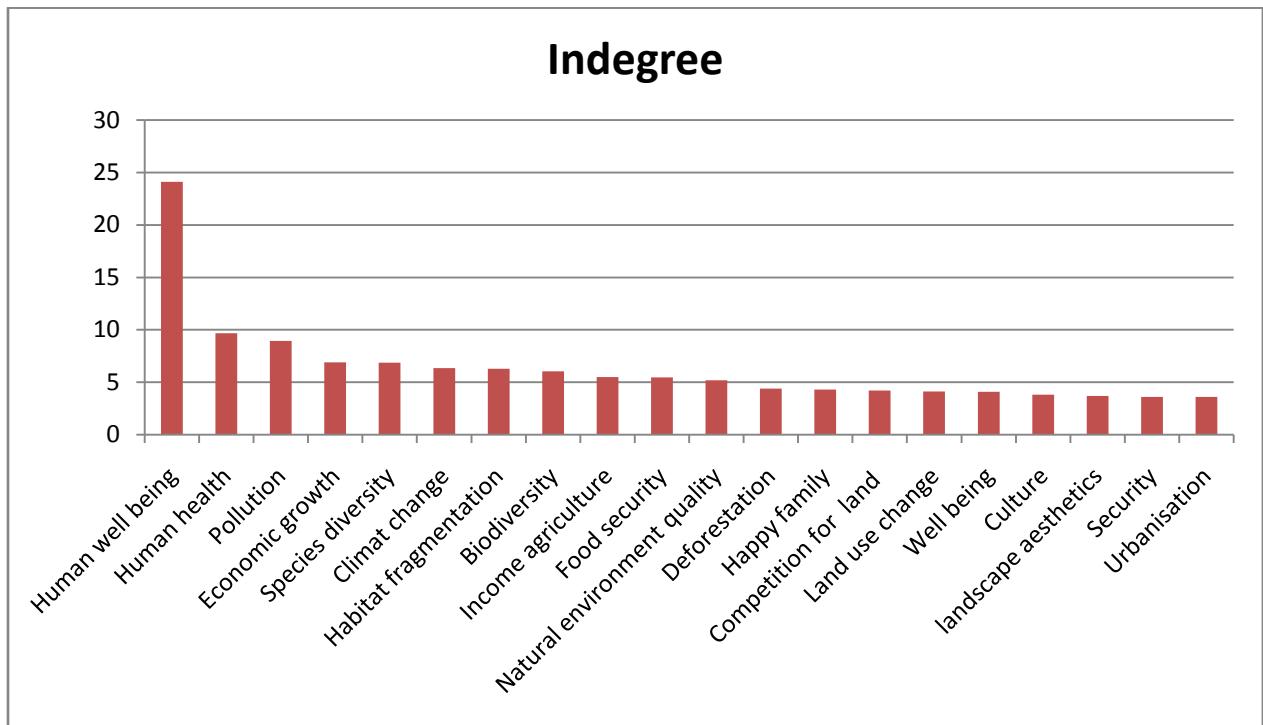

Figure 11: Concepts with the highest indegree in the aggregated map.

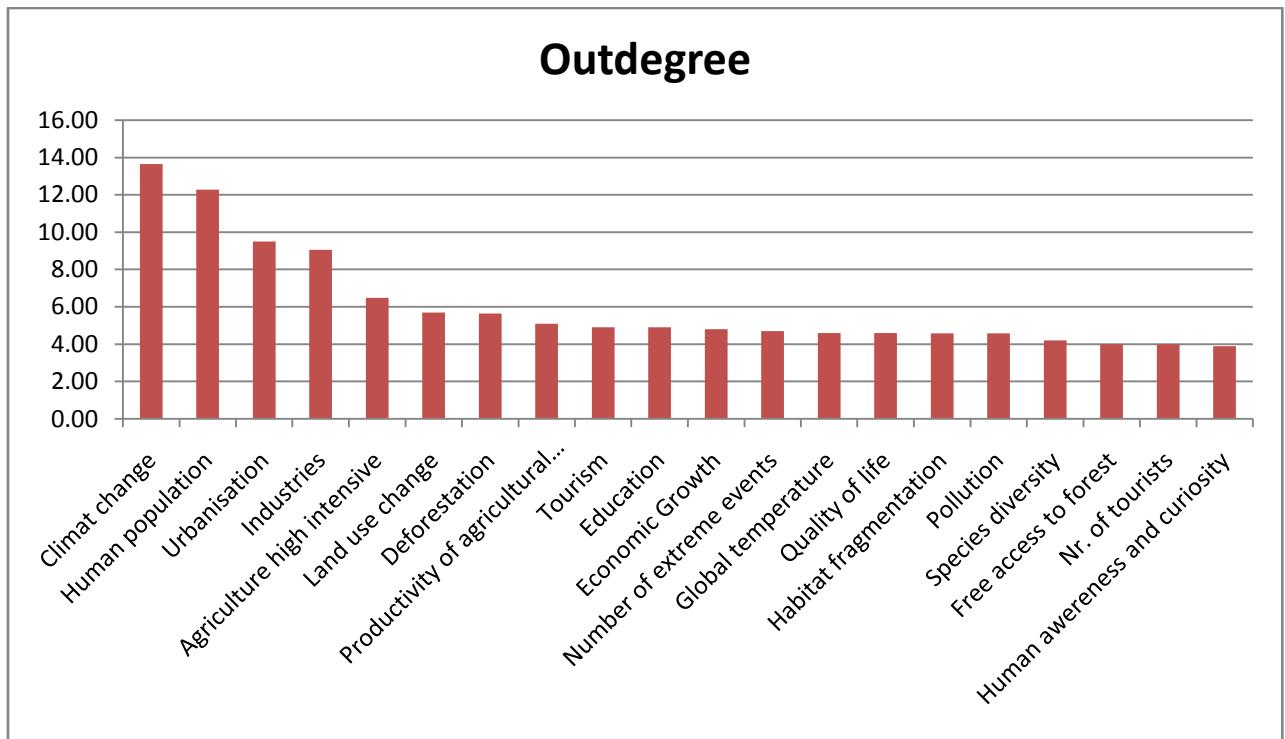

Figure 12: Concepts with the highest outdegree in the aggregated map.

Some details of the social map

Figure 13: All neighbors directly influencing and influenced by the concept “Human well being” and there inter-linkages. Red arrows indicate negative black positive relations. Colors are used as in fig. 9.

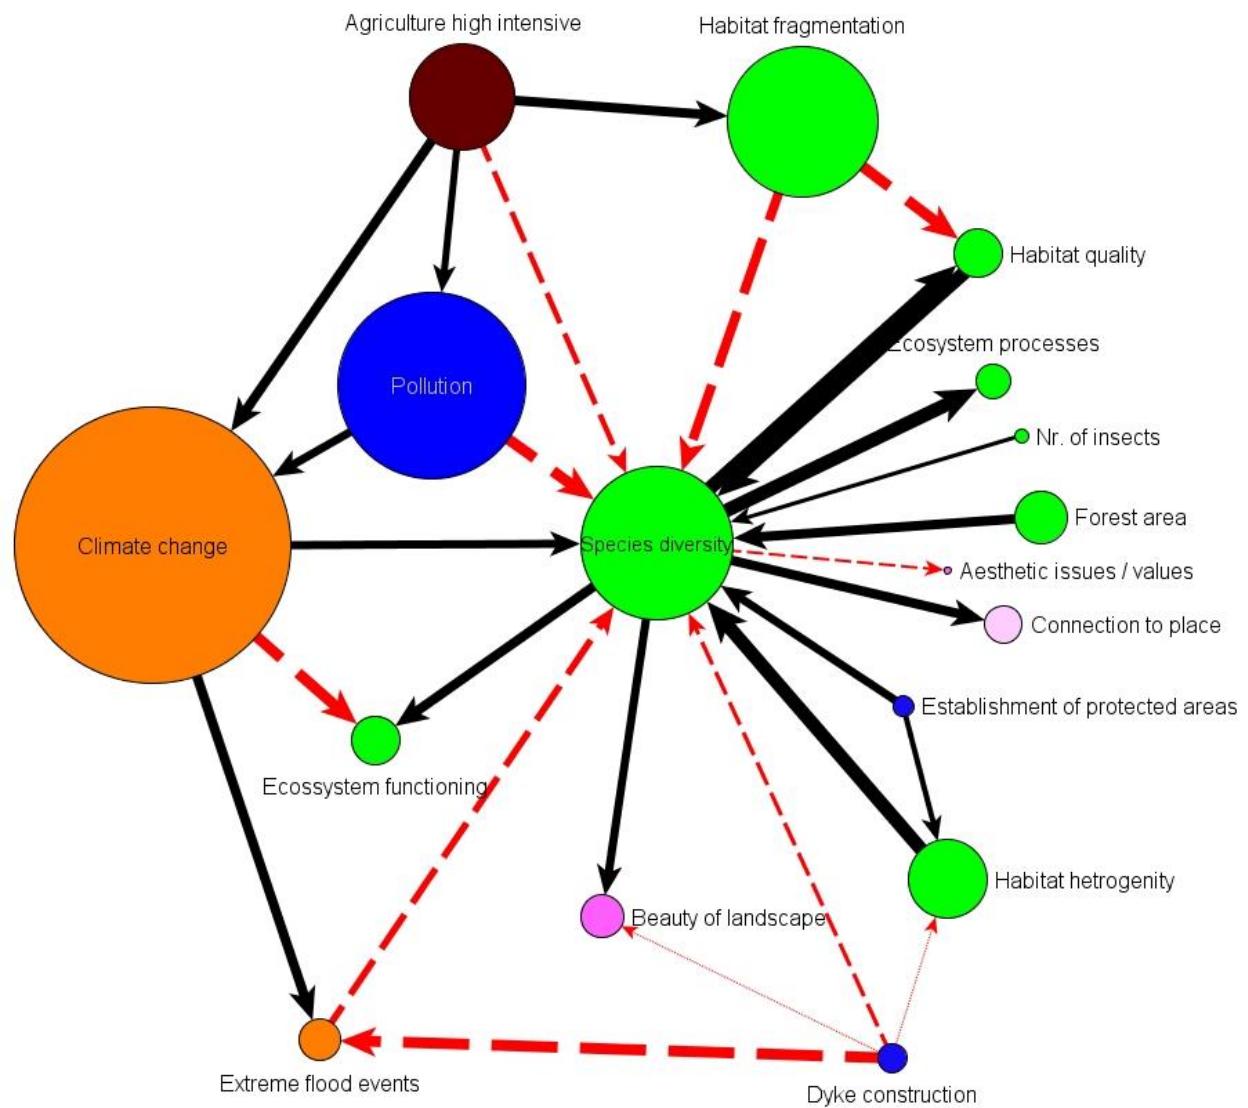

Figure 14: All neighbors directly influencing and influenced by the concept “Species diversity” and there inter-linkages. Red arrows indicate negative black positive relations. Colors are used as in fig. 9.

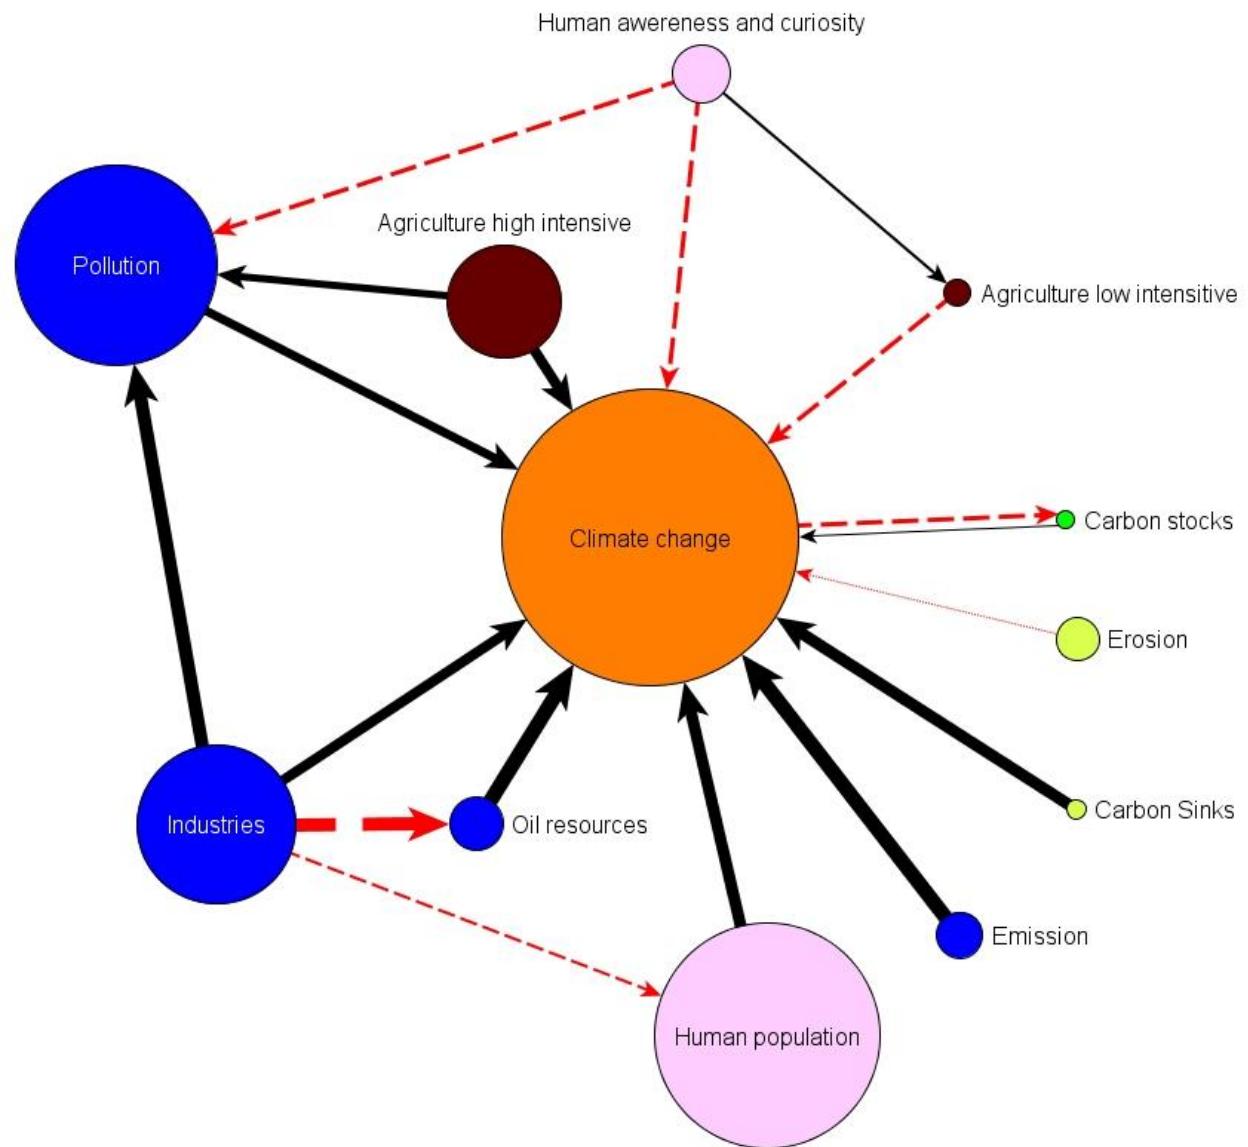

Figure 15: Direct neighbors influencing the concept “Climate Change”. Red arrows indicate negative black positive relations. Colors are used as in fig. 9.

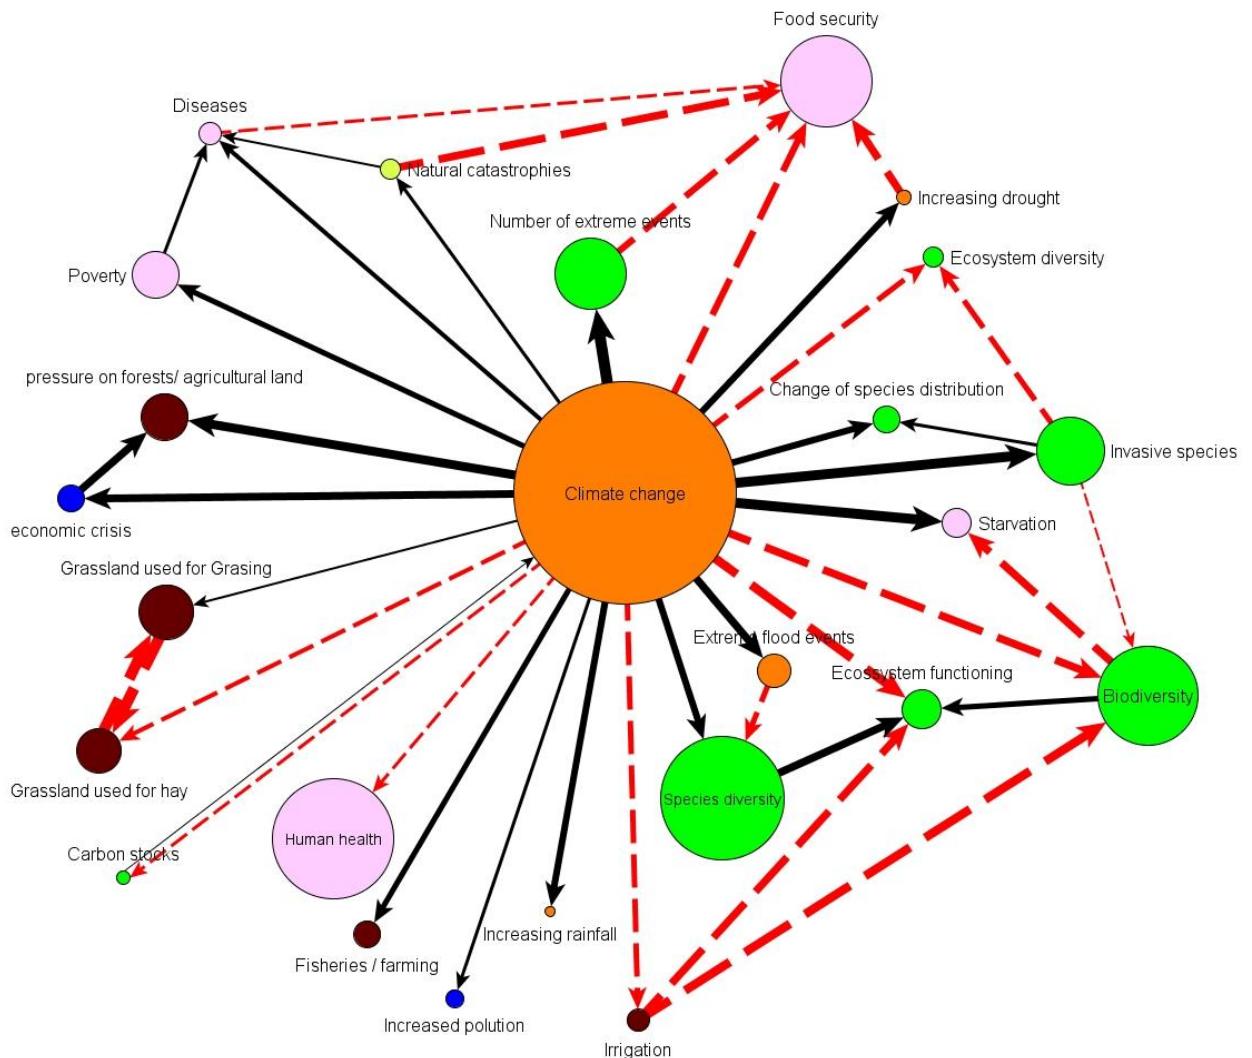

Figure 16: Direct neighbors influenced by the concept “Climate Change”. Red arrows indicate negative black positive relations. Colors are used as in fig. 9.

The Scenarios:

The results of the scenario runs for the Peyresq-Social-Map show relative meaningful results. Nevertheless there are also some concepts showing strange trends as one might aspect considering the relative un-facilitated mapping process and the different focuses of some of the maps.

“Lets grow!”

Storyline: Well we have all heard the talk of Martin Sharman. So what trends does the fuzzy cognitive model show if we assume that economic development, economic growth and human population will continue increasing? Will “Human Well Being” rise or will we face some serious problems?

Table 2: Factors manipulated in the scenario “Lets grow!”

Economic development	Set to 1
Economic Growth	Set to 1
Human population	Set to 1

Table 3: Results of the scenario “Lets grow!”. Factors with a positive trend are listed in the left column, factors with a negative trend in the right column. +++ / --- (red color) indicates a strong change, +/ - a medium change (blue), + / - a weak change (purple) and ~ (grey) a very weak change.

“Science, Conservation & sustainable development”

Storyline: Let's assume that we manage to convince policy makers, and – may be even more important - the general public, that sustainability and nature conservation are really important. Science on the other side works well in predicting changes and in communicating important issues. All this is backed up by subsidy incentivizes and mechanisms that help to successfully enforce policies.

Table 4: Factors manipulated in the scenario “Science, Conservation & sustainable development”

Change was predicted	Set to 1
Communication and information programs	Set to 1
Conservation efforts	Set to 1
Establishment of protected areas	Set to 1
Natura 2000	Set to 1
Scientist	Set to 1
Subsidies incentives	Set to 1
Success of policy enforcement	Set to 1
Sustainable agriculture	Set to 1
Sustainable consumption	Set to 1

Table 5: Results of the scenario “Science, Conservation & sustainable development”. Factors with a positive trend are listed in the left column, factors with a negative trend in the right column. +++ / --- (red color) indicates a strong change, +- - a medium change (blue), + / - a weak change (purple) and ~ (grey) a very weak change.

Acknowledgment

I would like to thank all the students of the 2009 ALTER-Net Summer School for participating in the FCM exercise. Also all the speakers who gave inspiring talks, shared their thoughts or gave furious Scottish dance lessons.

And last but not least: Special thanks to Allan, Sabine and Wolfgang who made this great summer school possible!
